How the Obscure Science of Rubbing Built the Past and Will Shape the Future

From paint remover to clean injection molding, rubber has a long and fascinating relationship with friction.

BY MATTHEW ROBINSON | MAY 1, 2022

As early as the Stone Age, humans realized if they painstakingly created a dry wooden stick back and forth in the hollow of a limb, they could successfully start a fire. Friction has been responsible for the development of wheels, axles, lines, and wires allowed for easier transport of building materials and increased the speed of their chariots. And in the Bible, Noah sealed his ark with bitumen to make the vessel more hydrophobic.

These are all early examples of building engineers practicing "tribology" (from the Greek word *τριβος*, "to rub"), the field devoted to the study and interesting surfaces in relative motion, including friction, corrosion, and lubrication.

It may sound like another obscure "science" at first. But from a grandfather clock's or molecular protein's to a roller coaster, every system is made up of connected parts—rivets, gears, bearings, hose, wheels—that create friction and can break down without proper lubrication. The velocity created between these parts as they rub together can lead to removal of material at the surface, that is, to wear and tear.

While tribologists—specialists who work in the field—have traditionally focused on fatigue, wear, or failure in mechanical elements like these, recent developments in the field have pushed this little known branch of science into the spotlight. In fact, tribology's influence on global energy consumption, emissions, healthcare and sustainability has never been more immediate.

Tribology's applications now extend beyond the realm of mechanical engineering to include the study of friction between the skin and natural ball-and-socket leg joint with a smooth metallic ball at the head of the femur. Geerthaga considers the friction of textured plates and giant plankes, while nanotribology examines phenomena at a microscopic scale—club drive storage, diamond-reinforced materials, even molecular stress. Most recently, green tribology seeks to address environmental problems such as how to lubricate the mechanisms of a wind turbine.

How can a field so pervasive in nature and everyday life remain virtually invisible to the general public, science? In part, because tribology itself is built on seven forms of around us.

Tribology is hiding in plain sight.

Tribology Through the Centuries

While the term wasn't coined until the 1960s, tribology's first scholar lived over 500 years ago. Leonardo da Vinci wasn't just an artist genius, but a keen observer and engineer who understood friction was a limiting factor in the efficiency of his revolutionary machines. The artist's sketches—astutely dissimilar as doodles and i.e.g technology proved otherwise—distinguished between rolling and sliding contacts and identified surface roughness as a factor in material movement.

Nearly two centuries later, French physicist Guillaume Amontons published his findings on friction, later that generic sliding surfaces and lubrication research today in his 1667 work *Principes*, for Isaac Newton laid down the foundations of fluid viscosity, which led to the development of lubricants. The observations and experiments carried out by Leonardo, Amontons, and Newton form the basis for many modern tribological devices, from car brakes to shoe soles.

It's perhaps surprising that anyone would devote a lifetime to the study of friction. But tribology. Our most impressive subject no one has heard of" is actually a significant part of daily life. Each block of ice an it lubricated with water, each step we take requires grip, safety fabricates the fund that we

Surfaces as varied as yoga mats and iPhone touch screens are carefully calibrated for our touch, designed to be neither too slick nor too sticky. Coins become worn as a result of continued contact with human fingers; the metal filings in our teeth grind down, our kitchen knives dull with use and the rubber treads of our car tires wear out. Wear is such a universal phenomenon that rarely do two solid bodies slide over each other or even touch each other without measurable material transfer or material loss. But we often don't consider such problems until we encounter them.

"Tribology is an afterthought; a technology used to solve a problem whenever there's a new mechanical system," Chris DeGarmo, senior scholarship at NASA Glenn Research Center, tells Popular Mechanics.

DeGarmo works on complex friction wear and lubrication problems across aeronautics and space missions: bearings that can turn at cold temperatures, and lubricants that can endure the high vacuum of space, withstand the dramatic vibrations of a rocket launch, and survive heat generated by aircraft turbines and engines.

"I like to tell people that my job is to make sure that things that are supposed to move keep moving, and things that aren't supposed to move don't," DeGarmo explains. Advances in tribology, he adds, typically occur whenever society runs into its something new.

"MY JOB IS TO MAKE SURE THAT THINGS THAT ARE SUPPOSED TO MOVE KEEP MOVING, AND THINGS THAT AREN'T SUPPOSED TO MOVE DON'T."

Consider that mankind's earliest, and arguably most important inventions—fire, and the wheel—were actually attempts to work out tribological obstacles. The creation of the required friction, while the wheel was a way to reduce friction. Millennia later, we continue to puzzle over these same basic principles.

RELATED STORY

Why This is the Greatest Tool of All Time

In the 1990s, for example, when computer hard disk drives frequently crashed, tribologists developed fluorinated oils and diamond coatings to reduce friction between the read/write heads and magnetic recording media during startup or slowdown. More recently, engineers discovered wind turbines welcomed by greater gusts on actual monstrosities than inside sensing incident, which frequently led to their overload and breakdown. Better controls, special coatings and bearing alloys developed by tribologists allowed wind turbines to withstand high winds, which in turn conserved energy. In effect, innovations like these solve tribological problems and simultaneously reveal them.

Unimagined tribological challenges are the future. Will electric cars generate spark discharges when we drive them across a wet road? Will another aerodrome unfurl properly in outer space? Will Mars little provide amperes with durable freedom of movement? Will the Venere we eventually land on Venus be able to withstand the hell of spewing mechanical sensitivities—be able to withstand the extreme temperatures, corrosive acids and chemical dust storms of that alien environment?

"PEOPLE ASSUME THAT A CAR OR WIND CAN BE UNTIRING." BUT DIFFERENT SYSTEMS REQUIRE A WIDE VARIETY OF LUBRICANTS. CLEARY OIL CAN'T WORK IT AROUND ME.

"Tribology's much to be beyond comprehension," says Ivan Zabowski, Senior Technical Advisor at TriboFil and a member of the Society of Tribologists and Lubricants Engineers (STLE), a group of scientists and academics established in 1944. Zabowski leads training programs in lubricant technology and tribological problem-solving and consulting as well as industry best practices. Most of his course sessions have been filled Zabowski with the subject, he says, and they often arrive armed with misunderstandings and so-called "tribology myths."

"People assume that a car or MOAD can do anything," Zabowski tells *Popular Mechanics*. "They rely on faulty wisdom passed down through the ages, as those 20th-Lube stickers that warn them to change their engine after 3000 miles." But different systems, in fact, require a wide variety of lubricants, often grease won't always do.

Biological, maritime, and aeronautical systems, for example, rely on a wide range of "third body" lubricants—that is, the slippery medium sandwiched between two hard surfaces. Magnetic levitation between interstellar bodies and Earth's atmosphere, for instance, requires electromagnetic lubricants. Sponge systems may use air lubricants, and ship propellers are water and rubber bearings instead of metal to maximize energy efficiency and minimize corrosion.

To solve this problem of the third body in resistance, tribologists often look to the natural world. In Indy Olympic swimmers minimize drag in the water, for instance, tribologists turned to one of the most efficient swimmers on earth: the shark.

How Animals Shaped Our Modern World

"By studying sharks, we developed a low drag swimsuit that reduced friction by nearly a quarter," says Zabowski. In fact, the shark skin-modeled suit helped athletes break 20 world records. Officials ultimately decided to ban its use, claiming an unfair advantage versus their rivals, yet the suit was a remarkable illustration of tribology's potential to improve quality of life. "While it appears we were too late, this also showed we have much to gain," says Zabowski.

Beyond the world of industrial engineering, tribology remains an almost social science. Most feel the idea more theoretical than practical, especially given that the physics of surfaces is hard to describe or measure. "There's lack of awareness because the technology is so diffused," says Zabowski.

Indeed, tribology is a highly interdisciplinary field. It's a branch of study made up of mechanical engineering, materials science, biology, mathematics, and chemistry. Tribologists, tribological problem-solvers—everything from adhesive tribologists to bearing shock-lit authority—to humidity's effect on metallurgy—are often referred with practical, solid-to-stone solutions, making them harder to identify.

RELATED STORY

How to Give Yourself to a Plane

As one of the earliest forms of resource conservation, tribology has, somewhat paradoxically, spurred incredible energy usage. Extending the service life of machines often delays the adoption of newer, more efficient designs. Yet, whether the aim is to prevent fatigue of our machines, protect equipment from corrosion, control temperature and contamination, transmit power, or provide a fluid seal, *science friction*, as it is, increasingly relevant across industries.

Tribological applications allow human beings to interact with their solid planet, overcome the inconvenience of excessive wear, and mitigate the loss of value and precious resources. "We will have economic of work about all of," Zabowski says, "but tribology continues to impact our lives in new and innovative ways."
